All cannabinoids in their acid forms (those ending in "-A") can be converted to their non-acid forms through a process called decarboxylation when the sample is heated. The molecules lose mass through this process, and thus to find the total theoretical active cannabinoids you must multiply the acid forms by 87.7%.

For example, THC-A can be converted to active THC using the formula:  $THC-A \times 0.877 = THC$

And so the Max THC for the sample is:  $Max\ THC = (THC-A \times 0.877) + HC$

This method has been validated according to the principles of the International Conference on Harmonisation.
